

Determination of the 7-day Mean Annual Low Flow (7-day MALF)

Data typically gathered every 15 minutes

Calculate the average flow over 7 days = ●

Do this each day to create a running average for each hydrological year of record (1July-30June)

Identify the lowest running 7day average each year for every year of record = ●

Take the average of all of these low flows over the entire record period (eg 15 years) = ●

This gives us the **7-day Mean Annual Low Flow** (7day MALF) for the total sampling record.
